

Business Problem:

One of the retail chains in USA looking to implement Tableau as its business intelligence needs. However, they have following requirements which they want to know if that is possible or not using Tableau.

The requirements are as follows:

1. Business looking for a quick reporting solution and as per them their data will get refresh on daily basis but that refresh will happen after 15 hours after the previous load. Now the requirement is that they does not want to have the connection with the live data and they want some snapshot which can be used while reporting.
2. One of the requirements is they need to filter the data at the very start so that there will be different reports for different types of user, lets say if you are a manager of East region you should connect to the report where only we help you see east data. (As of now we are not talking about row level security). Also in these reports they want the live data to be connected.
3. Also next year they are planning to expand the business to Europe so they want a solution which can take care of both the locations data for analysis.
